**Conference proceedings on 27th ACM/IEEE design automation conference** January 1991  
 This paper describes a circuit analysis program aimed at quickly solving linear interconnection circuits with inductance and coupling. It computes circuit responses to varying degrees of detail, varying from a simple Elmore delay to a good waveform estimate. Allowable circuit forms are much more flexible than for existing Elmore delay algorithms. Large networks or distributed lines can be reduced to a form of transfer function that can subsequently be analyzed much more efficiently with the ...

**Proceedings of the 35th annual conference on Design automation conference** May 1998  
 We describe powerful new techniques for the analysis of RF circuits. Next-generation CAD tools based on such techniques should enable RF designers to obtain a more accurate picture of how their circuits will operate. These new simulation capabilities will be essential in order to reduce the number of design iterations needed to produce complex RFICs.

The method of moments is an important tool for solving boundary integral equations arising in a variety of applications. It transforms the physical problem into a dense linear system. Due to the large number of variables and the associated computational requirements, these systems are solved iteratively using methods such as GMRES, CG and its variants. The core operation of these iterative solvers is the application of the system matrix to a vector. This requires  $O(n^2)$  operations and memory us ...

**Proceedings of the 1997 IEEE/ACM international conference on Computer-aided design** November 1997  
Integral equation techniques are often used to extract models of integrated circuit structures. This extraction involves solving a dense system of linear equations, and using direct solution methods is prohibitive for large problems. In this paper, we present IES/sup 3/ (pronounced "ice cube"), a fast Integral Equation Solver for three-dimensional problems with arbitrary kernels. Extraction methods based on IES/sup 3/ are substantially more efficient than existing multipole-based approaches.

 Abstract: Multipole-accelerated surface-volume methods have proved to be very efficient techniques for delay and cross-talk simulation of three-dimensional integrated circuit interconnect. However, to be efficiently combined with transistor circuitry in a SPICE-level simulation, reduced-order models which have accurate low-frequency behavior must be constructed. Asymptotic Waveform Evaluation (AWE) or Pade-via-Lanczos (PVL) algorithms can not be used directly to construct the reduced-order model ...

**Proceedings of the 35th annual conference on Design automation conference** May 1998  
 Because magnetic effects have a much longer spatial range than electrostatic effects, an interconnect line with large inductance will be sensitive to distant variations in interconnect topology. This long range sensitivity makes it difficult to balance delays in nets like clock trees, so for such nets inductance must be minimized. In this paper we use two- and three-dimensional electromagnetic field solvers to compare dedicated ground planes to a less area-consuming approach, interdigitatin ...
